Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

**Description**Cross-Reference

- 5 **[0001]** This application is a continuation-in-part of co-pending application Serial No. 07/311,969, filed February 17, 1989.

Field Of The Invention

- 10 **[0002]** The present invention relates to a process for isomerizing a waxy feed, including petroleum waxes, over a catalyst having a particular pore geometry and including at least one Group VIII metal to produce a lube oil having a low pour point and excellent viscosity and viscosity index properties.

Background Of The Invention

- 15 **[0003]** High-quality lubricating oils are critical for the operation of modern machinery and automobiles. Unfortunately, the supply of natural crude oils having good lubricating properties is not adequate for present demands. Due to uncertainties in world crude oil supplies, high-quality lubricating oils must be produced from ordinary crude feedstocks and can even be produced from paraffinic synthetic polymers. Numerous processes have been proposed for producing  
 20 lubricating oils that can be converted into other products by upgrading the ordinary and low-quality stocks.
- [0004]** It is desirable to upgrade a crude fraction otherwise unsuitable for lubricant manufacture into one from which good yields of lube oils can be obtained. Dewaxing is required when highly paraffinic oils are to be used in products which need to remain mobile at low temperatures, e.g., lubricating oils, heating oils and jet fuels. The higher molecular weight straight chain normal and slightly branched paraffins which are present in oils of this kind are waxes which  
 25 cause high pour points and high cloud points in the oils. If adequately low pour points are to be obtained, these waxes must be wholly or partly removed. In the past, various solvent removal techniques were used such as propane dewaxing and MEK dewaxing but these techniques are costly and time consuming. Catalytic dewaxing processes are more economical and achieve this end by selectively cracking the longer chain n-paraffins to produce lower molecular weight products, some of which may be removed by distillation.
- 30 **[0005]** Because of their selectivity, prior art dewaxing catalysts generally comprise an aluminosilicate zeolite having a pore size which admits the straight chain n-paraffins either alone or with only slightly branched chain paraffins (sometimes referred to herein as waxes), but which excludes more highly branched materials, cycloaliphatics and aromatics. Zeolites such as ZSM-5, ZSM-11, ZSM-12, ZSM-23, ZSM-35 and ZSM-38 have been proposed for this purpose in dewaxing processes and are described in U.S. Patents Nos. 3,894,938; 4,176,050; 4,181,598; 4,222,855; 4,229,282,  
 35 4,710,485 and 4,247,388, and EP-A-0209997. Such processes as are set forth in the above-mentioned patents are used to accomplish dewaxing on feeds which contain relatively low amounts of waxes, generally well below 50%, and they operate by selectively cracking the waxes. These processes are not readily adapted for treating high wax content feeds since, due to the large amount of cracking which occurs, such waxes would tend to be cracked to provide very low molecular weight products.
- 40 **[0006]** Since dewaxing processes of this kind function by means of cracking reactions, a number of useful products become degraded to lower molecular weight materials. For example, waxy paraffins may be cracked to butane, propane, ethane and methane as may the lighter n-paraffins which do not contribute to the waxy nature of the oil. Because these lighter products are generally of lower value than the higher molecular weight materials, it would obviously be desirable to limit the degree of cracking which takes place during a catalytic dewaxing process.
- 45 **[0007]** Although U.S. Patents Nos. 3,700,585; 3,894,938; 4,176,050; 4,181,598; 4,222,855; 4,222,282; 4,247,388 and 4,859,311 teach dewaxing of waxy feeds, the processes disclosed therein do not disclose a process for producing high yields of a lube oil having a very low pour point and high viscosity index from feeds containing a very high wax content, i.e., greater than 80% wax, such as slack wax, deoiled wax or synthetic liquid polymers such as low molecular weight polyethylene.
- 50 **[0008]** Also, the prior art does not disclose a lube oil characterized by having both a low pour point (below about -24°C) and a viscosity index greater than 125. It is believed that the closest that the prior art comes to accomplishing this is set forth in one or more of U.S. Patents 3,365,390 (pour point -23°C, viscosity index 124); 3,658,689 (pour point -54°C, viscosity index 92 as calculated from Table III of the patent); 3,764,516 (same as 3,658,689); 3,487,005 (pour point -29°C, viscosity index 121 and 125 and pour point -46°C, viscosity index 122) and 4,547,283 pour point not  
 55 specified but probably above 0°C as made by solvent dewaxing, viscosity index 154-156).
- [0009]** Since processes which remove wax will give a low yield with very waxy feeds, isomerization processes are preferred. U.S. Patent No. 4,734,539 discloses a method for isomerizing a naphtha feed using an intermediate pore size zeolite catalyst, such as an H-offretite catalyst. U.S. Patent No. 4,518,485 discloses a process for dewaxing a

hydrocarbon feedstock containing paraffins by a hydrotreating and isomerization process.

[0010] U.S. Patent No. 4,689,138 discloses an isomerization process for reducing the normal paraffin content of a hydrocarbon oil feedstock using a catalyst comprising an intermediate pore size silicoaluminophosphate molecular sieve containing a Group VIII metal component which is occluded in the crystals during growth.

5 [0011] Lube oils may also be prepared from feeds having a high wax content such as slack wax by an isomerization process. In prior art wax isomerization processes, however, either the yield is low and thus the process is uneconomical, or the feed is not completely dewaxed. When the feed is not completely dewaxed it must be recycled to a dewaxing process, e.g., a solvent dewaxer, which limits the throughput and increases cost. U.S. Patent No. 4,547,283 discloses  
10 converting wax to lube. However, the MEK dewaxing following isomerization disclosed therein severely limits pour reduction and thus, very low pour points cannot be achieved. Further, the catalyst disclosed therein is much less selective than the catalysts used in the present invention.

#### Summary Of The Invention

15 [0012] The present invention overcomes the problems and disadvantages of the prior art by providing a process for preparing a lube oil comprising isomerizing a waxy feed

1) having greater than 50% wax and/or

2) exhibiting a high pour point above °C and having greater than 70% paraffinic carbon

20 over a catalyst comprising an inorganic oxide molecular sieve having generally oval 1-D pores having a minor axis between 4.2Å and 4.8Å and a major axis between 5.4Å and 7.0Å as determined by X-ray crystallography and at least one Group VIII metal at a pressure of from 205 kPa (15 psig) to 13900 kPa (2000 psig).

25 [0013] It is an object of the invention to produce a lube oil having excellent viscosity and viscosity index properties and a very low pour point.

[0014] It is a further object of the invention to provide a lube oil having low frictional resistance.

[0015] It is an additional object of the invention to provide a lube oil which causes less engine wear than prior art mineral oils.

[0016] It is an additional object of the invention to provide a lube oil which provides increased fuel efficiency.

30 [0017] It is yet a further object of the invention to provide a lube oil having improved oxidation resistance compared to conventional mineral oils. The term "oxidation resistance" refers to the resistance of the oil to oxygen addition, i.e., how rapidly oxygen is picked up and added to molecular species within the oil. Oxidation resistance is indicated by the oxidator BN measured in hours. Oxidator BN measures the time required for 100 grams of oil to absorb one liter of oxygen and is described in U.S. Patent No. 3,852,207 at column 6, lines 15-30 which is incorporated herein by refer-  
35 ence.

[0018] Additional objects and advantages of the invention will be set forth in part in the description which follows, and in part will be obvious from the description, or may be learned by practice of the invention. The objects and advantages of the invention will be realized and attained by means of the instrumentalities and combinations, particularly pointed out in the appended claims.

40 [0019] In accordance with one embodiment the invention provides a process for producing a lube oil having excellent viscosity and viscosity index properties and a low pour point comprising isomerizing a waxy feed over a catalyst comprising an intermediate pore size silicoaluminophosphate molecular sieve and at least one Group VIII metal.

[0020] In accordance with another embodiment of the invention the catalyst in the process comprises an intermediate pore size ZSM-22, ZSM-23 or ZSM-35 zeolite.

45 [0021] The lube oil of the invention has a high paraffinic content which provides a low viscosity for its boiling range. Such properties result in less frictional resistance, less engine wear and increased fuel efficiency. The low viscosity and low pour point of the lube oil result in easier cold engine starting than prior art mineral oils. The lube oil has a high viscosity index ranging from 125 to 180 and a very low pour point, ranging from less than -63°C to -24°C. Since little or no viscosity index improver compositions or pour point depressant compositions are necessary for use with the lube  
50 oil of the invention, fewer performance-decreasing deposits are formed. The high paraffinic nature of the oil gives it improved oxidation resistance compared to conventional mineral oils.

#### Brief Description Of The Drawings

55 [0022] The invention will be better understood by reference to figures of the drawings wherein like numbers denote like parts throughout and wherein:

[0023] Figure 1 is a ternary diagram showing the compositional parameters of the silicoaluminophosphates of U.S. Patent No. 4,440,871 in terms of mole fractions of silicon, aluminum and phosphorus.

**[0024]** Figure 2 is a ternary diagram showing the preferred compositional parameters of the silicoaluminophosphates of mole fractions of silicon, aluminum and phosphorus.

**[0025]** Figure 3 is a plot of 700 F+ lube yield versus pour point for the process set forth in Example 3.

**[0026]** Figure 4 is a plot of viscosity index versus pour point for the process set forth in Example 3.

5

#### Detailed Description Of The Preferred Embodiments

**[0027]** Reference will now be made in detail to the present preferred embodiments of the invention.

**[0028]** As used herein, the term "waxy feed" includes petroleum waxes. The feedstock employed in the process of the invention preferably contains greater than 50% wax, more preferably greater than 80% wax, most preferably greater than 90% wax. However, a highly paraffinic feed having a high pour point, generally above 0°C, more usually above 10°C, but containing less than 50% wax is also suitable for use in the process of the invention. Such a feed should preferably contain greater than 70% paraffinic carbon, more preferably greater than 80% paraffinic carbon, most preferably greater than about 90% paraffinic carbon.

**[0029]** Exemplary additional suitable feeds for use in the process of the invention include waxy distillate stocks such as gas oils, lubricating oil stocks, synthetic oils such as those by

**[0030]** Fischer-Tropsch synthesis, high pour point polyalphaolefins, foos oils, synthetic waxes such as normal alphaolefin waxes, slack waxes, deoiled waxes and microcrystalline waxes. Foos oil is prepared by separating oil from the wax. The isolated oil is referred to as foos oil.

**[0031]** Feeds also suitable for use in the process of the invention are partially dewaxed oils wherein dewaxing to an intermediate pour point has been carried out by a process other than that claimed herein, for example, conventional catalytic dewaxing processes and solvent dewaxing processes. Exemplary suitable solvent dewaxing processes are set forth in U.S. Patent No. 4,547,287.

**[0032]** The process of the invention may also be employed in combination with conventional dewaxing processes to achieve a lube oil having particular desired properties. For example, the process of the invention can be used to reduce the pour point of a lube oil to a desired degree. Further reduction of the pour point can then be achieved using a conventional dewaxing process. Under such circumstances, immediately following the isomerization process of the invention, the lube oil may have a pour point greater than about 15°F (-9°C). Further, the pour point of the lube oil produced by the process of the invention can be reduced by adding pour point depressant compositions thereto.

**[0033]** The feedstock will normally be a C<sub>20</sub>+ feedstock generally boiling above about 600°F (316°C). However, the process of the invention is particularly useful with waxy distillate stocks such as gas oils, lubricating oil stocks, heating oils and other distillate fractions whose pour point and viscosity need to be maintained within certain specification limits. Lubricating oil stocks will generally boil above 230°C (450°F), more usually above 315°C (600°F). Hydroprocessed stocks are a convenient source of stocks of this kind and also of other distillate fractions since they normally contain significant amounts of waxy n-paraffins. The feedstock of the present process will normally be a C<sub>20</sub>+ feedstock containing paraffins, olefins, naphthenes, aromatics and heterocyclic compounds and a substantial proportion of higher molecular weight n-paraffins and slightly branched paraffins which contribute to the waxy nature of the feedstock. During processing, the n-paraffins and the slightly branched paraffins undergo some cracking or hydrocracking to form liquid range materials which contribute to a low viscosity product. The degree of cracking which occurs is, however, limited so that the yield of low boiling products is reduced, thereby preserving the economic value of the feedstock.

**[0034]** Slack wax can be obtained from either a hydrocracked lube oil or a solvent refined lube oil. Hydrocracking is preferred because that process can also reduce the nitrogen content to low values. With slack wax derived from solvent refined oils, deoiling can be used to reduce the nitrogen content. Optionally, hydrotreating of the slack wax can be carried out to lower the nitrogen content thereof. Slack waxes possess a very high viscosity index, normally in the range of from 140 to 200, depending on the oil content and the starting material from which the wax has been prepared. Slack waxes are therefore eminently suitable for the preparation of lubricating oils having very high viscosity indices, i.e., from about 120 to about 180.

**[0035]** The present invention provides a unique lube oil product as characterized by its combination of low pour point and high viscosity index. The lube oil is characterized by a pour point below -24°C (generally between -24°C and -63°C) and a viscosity index between 125 and 180, suitably greater than about 130. Preferably the pour point is below -30°C, more preferably below 40°C, and the viscosity index is greater than about 140.

**[0036]** While the process of the invention can be practiced with utility when the feed contains organic (nitrogen containing impurities), it is preferred that the organic nitrogen content of the feed be less than about 50 ppmw (parts per million by weight), more preferably less than about 10 ppmw. Particularly good results, in terms of activity and length of catalyst cycle (period between successive regenerations or start-up and first regeneration) are experienced when the feed contains less than about 10 ppmw of organic nitrogen.

**[0037]** The phrase "intermediate pore size", as used herein means an effective pore aperture in the range of from about 5.3 to about 6.5 Å when the porous inorganic oxide is in the calcined form. Molecular sieves having pore apertures

in this range tend to have unique molecular sieving characteristics. Unlike small pore zeolites such as erionite and chabazite, they will allow hydrocarbons having some branching into the molecular sieve void spaces. Unlike larger pore zeolites such as the faujasites and mordenites, they can differentiate between n-alkanes and slightly branched alkanes, and larger branched alkanes having, for example, quaternary carbon atoms.

[0038] The effective pore size of the molecular sieves can be measured using standard adsorption techniques and hydrocarbonaceous compounds of known minimum kinetic diameters. See Breck, Zeolite Molecular Sieves, 1974 (especially Chapter 8); Anderson, et al., J. Catalysis 58, 114 (1979); and U.S. Patent No. 4,440,871, the pertinent portions of which are incorporated herein by reference.

[0039] In performing adsorption measurements to determine pore size, standard techniques are used. It is convenient to consider a particular molecule as excluded if it does not reach at least 95% of its equilibrium adsorption value on the molecular sieve in less than about 10 minutes ( $p/p_0 = 0.5$ ;  $25^\circ\text{C}$ ).

[0040] Intermediate pore size molecular sieves will typically admit molecules having kinetic diameters of 5.3 to 6.5 Å with little hindrance. Examples of such compounds (and their kinetic diameters in Å) are: n-hexane (4.3), 3-methylpentane (5.5), benzene (5.85), and toluene (5.8). Compounds having kinetic diameters of about 6 to 6.5 Å can be admitted into the pores, depending on the particular sieve, but do not penetrate as quickly and in some cases are effectively excluded. Compounds having kinetic diameters in the range of 6 to 6.5 Å include: cyclohexane (6.0), 2,3-dimethylbutane (6.1), and m-xylene (6.1). Generally, compounds having kinetic diameters of greater than about 6.5 Å do not penetrate the pore apertures and thus are not absorbed into the interior of the molecular sieve lattice. Examples of such larger compounds include: o-xylene (6.8), 1,3,5-trimethylbenzene (7.5), and tributylamine (8.1).

[0041] The preferred effective pore size range is from about 5.5 to about 6.2 Å.

[0042] While the effective pore size as discussed above is important to the practice of the invention not all intermediate pore size molecular sieves having such effective pore sizes are advantageously usable in the practice of the present invention. Indeed, it is essential that the intermediate pore size molecular sieve catalysts used in the practice of the present invention have a very specific pore shape and size as measured by X-ray crystallography. First, the intracrystalline channels must be parallel and must not be interconnected. Such channels are conventionally referred to as 1-D diffusion types or more shortly as 1-D pores. The classification of intrazeolite channels as 1-D, 2-D and 3-D is set forth by R. M. Barrer in Zeolites, Science and Technology, edited by F. R. Rodrigues, L. D. Rollman and C. Naccache, NATO ASI Series, 1984 which classification is incorporated in its entirety by reference (see particularly page 75). Known 1-D zeolites include cancrinite hydrate, laumontite, mazzite, mordenite and zeolite L.

[0043] None of the above listed 1-D pore zeolites, however, satisfies the second essential criterion for catalysts useful in the practice of the present invention. This second essential criterion is that the pores must be generally oval in shape, by which is meant the pores must exhibit two unequal axes referred to herein as a minor axis and a major axis. The term oval as used herein is not meant to require a specific oval or elliptical shape but rather to refer to the pores exhibiting two unequal axes. In particular, the 1-D pores of the catalysts useful in the practice of the present invention must have a minor axis between about 4.2 Å and about 4.8 Å and a major axis between about 5.4 Å and about 7.0 Å as determined by conventional X-ray crystallography measurements.

[0044] The catalyst used in the isomerization process of the invention has an acidic component and a platinum and/or palladium hydrogenation component. In accordance with one embodiment of the invention the acidic component can suitably comprise an intermediate pore size silicoaluminophosphate molecular sieve which is described in U.S. Patent No. 4,440,871, the pertinent disclosure of which is incorporated herein by reference.

[0045] The most preferred intermediate pore size silicoaluminophosphate molecular sieve for use in the process of the invention is SAPO-11. SAPO-11 comprises a molecular framework of corner-sharing  $[\text{SiO}_2]$  tetrahedra,  $[\text{AlO}_2]$  tetrahedra and  $[\text{PO}_2]$  tetrahedra, [i.e.,  $(\text{Si}_x\text{Al}_y\text{P}_z)\text{O}_2$  tetrahedral units]. When combined with a platinum or palladium hydrogenation component, the SAPO-11 converts the waxy components to produce a lubricating oil having excellent yield, very low pour point, low viscosity and high viscosity index.

[0046] SAPO-11 comprises a silicoaluminophosphate material having a three-dimensional microporous crystal framework structure of  $[\text{PO}_2]$ ,  $[\text{AlO}_2]$  and  $[\text{SiO}_2]$  tetrahedral units whose unit empirical formula on an anhydrous basis is:

wherein "R" represents at least one organic templating agent present in the intracrystalline pore system; "m" represents the moles of "R" present per mole of  $(\text{Si}_x\text{Al}_y\text{P}_z)\text{O}_2$  and has a value of from zero to about 0.3, "x", "y" and "z" represent respectively, the mole fractions of silicon, aluminum and phosphorous, said mole fractions being within the compositional area bounded by points A, B, C, D and E on the ternary diagram of Figure 1 or preferably within the area bounded by points a, b, c, d and e on the ternary diagram of Figure 2. The silicoaluminophosphate has a characteristic X-ray powder diffraction pattern which contains at least the d-spacings (as-synthesized and calcined) set forth below in Table

# EP 0 536 325 B1

I. When SAPO-11 is in the as-synthesized form "m" preferably has a value of from 0.02 to 0.3.

TABLE I

2θ		d(Å)	Relative Intensity
9.4 - 9.65	(doublet)	9.41 - 9.17	m
20.3 - 20.6		4.37 - 4.31	m
21.0 - 21.3		4.23 - 4.17	vs
22.1 - 22.35		4.02 - 3.99	m
22.5 - 22.9		3.95 - 3.92	m
23.15 - 23.35		3.84 - 3.81	m-s

All of the as-synthesized SAPO-11 compositions for which X-ray powder diffraction data have been obtained to date have patterns which are within the generalized pattern of Table II below.

[0047] These values were determined by standard techniques. The radiation was the K-alpha doublet of copper and a diffractometer equipped with a scintillation counter and an associated computer was used. The peak heights, I, and the positions as a function of 2θ, where θ is the Bragg angle, were determined using algorithms on the computer associated with the spectrometer. From these, the relative intensities, 100 I/I<sub>o</sub>, where I<sub>o</sub> is the intensity of the strongest line or peak, and d (obs.) the interplanar spacing in Angstroms, corresponding to the recorded lines, were determined. In the Tables, the relative intensities are given in terms of the symbols vs = very strong, s = strong, m = medium, w = weak, etc.

[0048] Another intermediate pore size silicoaluminophosphate molecular sieve preferably used in the process of the invention is SAPO-31. SAPO-31 comprises a silicoaluminophosphate having a three-dimensional microporous crystal framework of [PO<sub>2</sub>], [AlO<sub>2</sub>] and [SiO<sub>2</sub>] tetrahedral units whose unit empirical formula on an anhydrous basis is:

wherein R represents at least one organic templating agent present in the intracrystalline pore system; "m" represents the moles of "R" present per mole of (Si<sub>x</sub>Al<sub>y</sub>P<sub>z</sub>)O<sub>2</sub> and has a value of from zero to 0.3; "x", "y" and "z" represent respectively, the mole fractions of silicon, aluminum and phosphorous, said mole fractions being within the compositional area bounded by points A, B, C, D and E on the ternary diagram of Figure 1, or preferably within the area bounded by points a, b, c, d and e on the ternary diagram of Figure 2. The silicoaluminophosphate has a characteristic X-ray powder diffraction pattern (as-synthesized and calcined) which contains at least the d-spacings set forth below in Table III. When SAPO-31 is in the as-synthesized form, "m" preferably has a value of from 0.02 to 0.3.

TABLE III

2 $\theta$	d(1) d(Å)	Relative Intensity
8.5 - 8.6	10.40 - 10.28	m - s
20.2 - 20.3	4.40 - 4.37	m
21.9 - 22.1	4.06 - 4.02	w - m
22.6 - 22.7	3.93 - 3.92	vs
31.7 - 31.8	3.823 - 2.814	w - m

All of the as-synthesized SAPO-31 compositions for which X-ray powder diffraction data have presently been obtained have patterns which are within the generalized pattern of Table IV below.

TABLE IV

[0049] SAPO-41, also suitable for use in the process of the invention, comprises a silicoaluminophosphate having a three-dimensional microporous crystal framework structure of  $[\text{PO}_2]$ ,  $[\text{AlO}_2]$  and  $[\text{SiO}_2]$  tetrahedral units, and whose unit empirical formula on an anhydrous basis is:

wherein R represents at least one organic templating agent present in the intracrystalline pore system; "m" represents the moles of "R" present per mole of  $(\text{Si}_x\text{Al}_y\text{P}_z)\text{O}_2$  and has a value of from zero to 0.3; "x", "y" and "z" represent respectively, the mole fractions of silicon, aluminum and phosphorous, said mole fractions being within the compositional area bounded by points A, B, C, D and E on the ternary diagram of Figure 1, or preferably within the area bounded by points a, b, c, d and e on the ternary diagram of Figure 2, and said silicoaluminophosphate having a characteristic X-ray powder diffraction pattern (as-synthesized and calcined) which contains at least the d-spacings set forth below in Table V. When SAPO-41 is in the as-synthesized form "m" preferably has a value of from 0.02 to 0.03.

TABLE V

$2\theta$	$d(\text{\AA})$	Relative Intensity
13.6 - 13.8	6.51 - 6.42	w - m
20.5 - 20.6	4.33 - 4.31	w - m

[0050] The process of the invention may also be carried out using a catalyst comprising an intermediate pore size nonzeolitic molecular sieve containing  $\text{AlO}_2$  and  $\text{PO}_2$  tetrahedral oxide units, and at least one Group VIII metal. Exemplary suitable intermediate pore size nonzeolitic molecular sieves are set forth in European patent Application No. 158,977 which is incorporated herein by reference.

[0051] The group of intermediate pore size zeolites of the present invention include ZSM-22, ZSM-23 and ZSM-35. These catalysts are generally considered to be intermediate pore size catalysts based on the measure of their internal structure as represented by their Constraint Index. Zeolites which provide highly restricted access to and egress from their internal structure have a high value for the Constraint Index, while zeolites which provide relatively free access to the internal zeolite structure have a low value for their Constraint Index. The method for determining Constraint Index is described fully in U.S. Patent No. 4,016,218 which is incorporated herein by reference.

[0052] Those zeolites exhibiting a Constraint Index value within the range of from about 1 to about 12 are considered to be intermediate pore size zeolites. Zeolites which are considered to be in this range include ZSM-5, ZSM-11, etc. Upon careful examination of the intermediate pore size zeolites, however, it has been found that not all of them are efficient as a catalyst for isomerization of a paraffin-containing feedstock which are high in  $\text{C}_{20+}$  paraffins, and preferably which are high in  $\text{C}_{22+}$  paraffins. In particular, it has been found that the group including ZSM-22, ZSM-23 and ZSM-35 used in combination with Group VIII metals can provide a means whereby a hydrocarbon feedstock having a paraffinic content with molecules of 20 carbon atoms or more undergoes unexpectedly efficient isomerization without destroying the ultimate yield of the feedstock.

[0053] It is known to use prior art techniques for formation of a great variety of synthetic aluminosilicates. These aluminosilicates have come to be designated by letter or other convenient symbols. One of the zeolites of the present invention, ZSM-22, is a highly siliceous material which includes crystalline three-dimensional continuous framework silicon containing structures or crystals which result when all the oxygen atoms in the tetrahedra are mutually shared between tetrahedral atoms of silicon or aluminum, and which can exist with a network of mostly  $\text{SiO}_2$ , i.e., exclusive of any intracrystalline cations. The description of ZSM-22 is set forth in full in U.S. Patent No. 4,556,477, U.S. Patent No. 4,481,177 and European Patent Application No. 102,716 the contents of which are incorporated herein by reference.

[0054] As indicated in U.S. Patent No. 4,566,477 the crystalline material ZSM-22 has been designated with a characteristic X-ray diffraction pattern as set forth in Table VII.

TABLE VII

Most Significant Lines of ZSM-22	
Interplanar d-spacings (Å)	Relative Intensity(I/I <sub>0</sub> )
10.9 ± 0.2	M - VS
8.7 ± 0.16	W
6.94 ± 0.10	W - M
5.40 ± 0.08	W
4.58 ± 0.07	W
4.36 ± 0.07	VS
3.68 ± 0.05	VS
3.62 ± 0.05	S - VS
3.47 ± 0.04	M - S
3.30 ± 0.04	W
2.74 ± 0.02	W
2.52 ± 0.02	W

It should be understood that the X-ray diffraction pattern of Table VII is characteristic of all the species of ZSM-22 zeolite compositions. Ion exchange of the alkali metal cations with other ions results in a zeolite which reveals substantially the same X-ray diffraction pattern with some minor shifts in interplanar spacing and variation in relative intensity.

[0055] Furthermore, the original cations of the as-synthesized ZSM-22 can be replaced at least in part by other ions using conventional ion exchange techniques. It may be necessary to precalcine the ZSM-22 zeolite crystals prior to ion exchange. In accordance with the present invention, the replacement ions are those taken from Group VIII of the Periodic Table, especially platinum, palladium, iridium, osmium, rhodium and ruthenium.

[0056] ZSM-22 freely sorbs normal hexane and has a pore dimension greater than about 4 Å. In addition, the structure of the zeolite provides constrained access to larger molecules. The Constraint Index as determined by the procedure set forth in U.S. Patent No. 4,016,246 for ZSM-22 has been determined to be from about 2.5 to about 3.0.

[0057] Another zeolite which can be used with the present invention is the synthetic crystalline aluminosilicate referred to as ZSM-23, disclosed in U.S. Patent No. 4,076,842, the contents of which are incorporated herein by reference. The ZSM-23 composition has a characteristic X-ray diffraction pattern as set forth herein in Table VIII.

[0058] Other molecular sieves which can be used with the present invention include, for example, Theta-1, as described in U.S. Patents 4,533,649 and 4,836,910, both of which are incorporated in their entireties by reference, Nu-10, as described in European Patent Application 065,400 which is incorporated in its entirety by reference and SSZ-20 as described in U.S. Patent 4,483,835 which is incorporated in its entirety by reference.

TABLE VIII

d(Å)	I/I <sub>0</sub>

3.44 ± 0.07	S
3.36 ± 0.07	W
3.16 ± 0.07	W
3.05 ± 0.06	W

TABLE VIII (continued)

d(Å)	I/I <sub>o</sub>
2.99 ± 0.06	W
2.85 ± 0.06	W
2.54 ± 0.05	M
2.47 ± 0.05	W
2.40 ± 0.05	W
2.34 ± 0.05	W

[0059] The ZSM-23 composition can also be defined in terms of mole ratios of oxides in the anhydrous state as follows:

wherein M is at least 1 cation and n is the valence thereof. As in the ZSM-22, the original cations of as-synthesized ZSM-23 can be replaced in accordance with techniques well-known in the art, at least in part by ionic exchange with other cations. In the present invention these cations include the Group VIII metals as set forth hereinbefore.

[0060] The third intermediate pore size zeolite which has been found to be successful in the present invention is ZSM-35, which is disclosed in U.S. Patent No. 4,016,245, the contents of which are incorporated herein by reference. The synthetic crystalline aluminosilicate known as ZSM-35, has a characteristic X-ray diffraction pattern which is set forth in U.S. Patent No. 4,016,245. ZSM-35 has a composition which can be defined in terms of mole ratio of oxides in the anhydrous state as follows:

wherein R is organic nitrogen-containing cation derived from ethylenediamine or pyrrolidine and M is an alkali metal cation. The original cations of the as-synthesized ZSM-35 can be removed using techniques well known in the art which includes ion exchange with other cations. In the present invention the cation exchange is used to replace the as-synthesized cations with the Group VIII metals set forth herein. It has been observed that the X-ray diffraction pattern of ZSM-35 is similar to that of natural ferrierite with a notable exception being that natural ferrierite patterns exhibit a significant line at 1.33 Å.

[0061] X-ray crystallography of SAPO-11, SAPO-31, SAPO-41, ZSM-22, ZSM-23 and ZSM-35 shows these molecular sieves to have the following major and minor axes: SAPO-11, major 6.7 Å, minor 4.4 Å; (Benett, J. M., et al, Zeolites, 1, 160(87)), SAPO-31 and SAPO-41, believed to be slightly large than SAPO-11, ZSM-22, major 5.5 Å, minor 4.5 Å (Kokotailo, G. T., et al, Zeolites, 5, 349(85)); ZSM-23, major 5.6 Å, minor 4.5 Å; ZSM-35, major 5.4 Å, minor 4.2 Å (Meier, W. M. and Olsen, D. H., Atlas of Zeolite Structure Types, Butterworths, 1987).

[0062] The intermediate pore size molecular sieve is used in admixture with at least one Group VIII metal. Preferably the Group VIII metal is selected from the group consisting of at least one of platinum and palladium and optionally, other catalytically active metals such as molybdenum, nickel, vanadium, cobalt, tungsten, zinc and mixtures thereof. Most preferably, the Group VIII metal is selected from the group consisting of at least one of platinum and palladium. The amount of metal ranges from about 0.01% to about 10% by weight of the molecular sieve, preferably from about 0.2% to about 5% by weight of the molecular sieve. The techniques of introducing catalytically active metals into a molecular sieve are disclosed in the literature, and preexisting metal incorporation techniques and treatment of the molecular sieve to form an active catalyst such as ion exchange, impregnation or occlusion during sieve preparation are suitable for use in the present process. Such techniques are disclosed in U.S. Patent Nos. 3,236,761; 3,226,339; 3,236,762; 3,620,960; 3,373,109; 4,202,996; 4,440,781 and 4,710,485 which are incorporated herein by reference.

[0063] The term "metal" or "active metal" as used herein means one or more metals in the elemental state or in some form such as sulfide, oxide and mixtures thereof. Regardless of the state in which the metallic component actually exists, the concentrations are computed as if they existed in the elemental state.

[0064] The catalyst may also contain metals which reduce the number of strong acid sites on the catalyst and thereby lower the selectivity for cracking versus isomerization. Especially preferred are the Group IIA metals such as magnesium and calcium.

[0065] It is preferred that relatively small crystal size catalyst be utilized in practicing the invention. Suitably, the average crystal size is no greater than about 10μ, preferably no more than about 5μ, more preferably no more than

about 1 $\mu$  and still more preferably no more than about 0.5 $\mu$ .

**[0066]** Strong acidity may also be reduced by introducing nitrogen compounds, e.g., NH<sub>3</sub> or organic nitrogen compounds, into the feed; however, the total nitrogen content should be less than 50 ppm, preferably less than 10 ppm. The physical form of the catalyst depends on the type of catalytic reactor being employed and may be in the form of a granule or powder, and is desirably compacted into a more readily usable form (e.g., larger agglomerates), usually with a silica or alumina binder for fluidized bed reaction, or pills, prills, spheres, extrudates, or other shapes of controlled size to accord adequate catalyst-reactant contact. The catalyst may be employed either as a fluidized catalyst, or in a fixed or moving bed, and in one or more reaction stages.

**[0067]** The catalytic isomerization step of the invention may be conducted by contacting the feed with a fixed stationary bed of catalyst, with a fixed fluidized bed, or with a transport bed. A simple and therefore preferred configuration is a trickle-bed operation in which the feed is allowed to trickle through a stationary fixed bed, preferably in the presence of hydrogen.

**[0068]** The catalytic isomerization conditions employed depend on the feed used and the desired pour point. Generally, the temperature is from 200°C to 475°C, preferably from 250°C and to 450°C. The pressure is typically from 15 psig and to 2000 psig, preferably from 50 to 1000 psig, more preferably from 100 psig to 600 psig. The process of the invention is preferably carried out at low pressure. The liquid hourly space velocity (LHSV) is preferably from 0.1 to 20, more preferably from 0.1 to 5, and most preferably from 0.1 to 1.0. Low pressure and low liquid hourly space velocity provide enhanced isomerization selectivity which results in more isomerization and less cracking of the feed thus producing an increased yield.

**[0069]** Hydrogen is preferably present in the reaction zone during the catalytic isomerization process. The hydrogen to feed ratio is typically from about 500 to about 30,000 SCF/bbl (standard cubic feet per barrel), preferably from about 1,000 to about 10,000 SCF/bbl. Generally, hydrogen will be separated from the product and recycled to the reaction zone.

**[0070]** The intermediate pore size molecular sieve used in the isomerization step provides selective conversion of the waxy components to non-waxy components. During processing, isomerization of the paraffins occurs to reduce the pour point of the oil below that of the feed and form lube oil boiling range materials which contribute to a low pour point product having excellent viscosity index properties.

**[0071]** Because of the selectivity of the intermediate pore size molecular sieve used in the invention, the yield of low boiling products is reduced, thereby preserving the economic value of the feedstock.

**[0072]** The intermediate pore size molecular sieve catalyst can be manufactured into a wide variety of physical forms. The molecular sieves can be in the form of a powder, a granule, or a molded product, such as an extrudate having a particle size sufficient to pass through a 2-mesh (Tyler) screen and be retained on a 40-mesh (Tyler) screen. In cases wherein the catalyst is molded, such as by extrusion with a binder, the silicoaluminophosphate can be extruded before drying, or, dried or partially dried and then extruded.

**[0073]** The molecular sieve can be composited with other materials resistant to temperatures and other conditions employed in the isomerization process. Such matrix materials include active and inactive materials and synthetic or naturally occurring zeolites as well as inorganic materials such as clays, silica and metal oxides. The latter may be either naturally occurring or in the form of gelatinous precipitates, sols or gels including mixtures of silica and metal oxides. Inactive materials suitably serve as diluents to control the amount of conversion in the isomerization process so that products can be obtained economically without employing other means for controlling the rate of reaction. The molecular sieve may be incorporated into naturally occurring clays, e.g., bentonite and kaolin. These materials, i.e., clays, oxides, etc., function, in part, as binders for the catalyst. It is desirable to provide a catalyst having good crush strength because in petroleum refining, the catalyst is often subjected to rough handling. This tends to break the catalyst down into powder-like materials which cause problems in processing.

**[0074]** Naturally occurring clays which can be composited with the molecular sieve include the montmorillonite and kaolin families, which families include the sub-bentonites, and the kaolins commonly known as Dixie, McNamee, Georgia and Florida clays or others in which the main mineral constituent is halloysite, kaolinite, dickite, nacrite or anauxite. Fibrous clays such as halloysite, sepiolite and attapulgite can also be used as supports. Such clays can be used in the raw state as originally mined or initially subjected to calcination, acid treatment or chemical modification.

**[0075]** In addition to the foregoing materials, the molecular sieve can be composited with porous matrix materials and mixtures of matrix materials such as silica, alumina, titania, magnesia, silica-alumina, silica-magnesia, silica-zirconia, silica-thoria, silica-beryllia, silica-titania, titania-zirconia as well as ternary compositions such as silica-alumina-thoria, silica-alumina-titania, silica-alumina-magnesia and silica-magnesia-zirconia. The matrix can be in the form of a cogel.

**[0076]** The catalyst used in the process of this invention can also be composited with other zeolites such as synthetic and natural faujasites, (e.g., X and Y) erionites, and mordenites. It can also be composited with purely synthetic zeolites such as those of the ZSM series. The combination of zeolites can also be composited in a porous inorganic matrix.

**[0077]** It is often desirable to use mild hydrogenation referred to as hydrofinishing after isomerization to produce

more stable lubricating oils. Hydrofinishing is typically conducted at temperatures ranging from 190°C to 340°C, at pressures from 400 psig to 3000 psig, at space velocities (LHSV) from 0.1 to 20, and hydrogen recycle rates of from about 400 to about 1500 SCF/bbl. The hydrogenation catalyst employed must be active enough not only to hydrogenate the olefins, diolefins and color bodies within the lube oil fractions, but also to reduce the aromatic content. The hydrofinishing step is beneficial in preparing an acceptably stable lubricating oil.

[0078] Suitable hydrogenation catalysts include conventional metallic hydrogenation catalysts, particularly the Group VIII metals such as cobalt, nickel, palladium and platinum. The metals are typically associated with carriers such as bauxite, alumina, silica gel, silica-alumina composites, and crystalline aluminosilicate zeolites. Palladium is a particularly preferred hydrogenation metal. If desired, non-noble Group VIII metals can be used with molybdates. Metal oxides or sulfides can be used. Suitable catalysts are disclosed in U.S. Patent Nos. 3,852,207; 4,157,294; 3,904,513 and 4,673,487, which are incorporated herein by reference.

[0079] The high viscosity index lube oil produced by the process of the present invention can be used as a blending component to raise the viscosity index of lube oils to a higher value. Since yield decreases with increasing viscosity index in either hydrocracking or solvent refining, the use of an isomerized wax to increase the viscosity index improves yield.

[0080] The invention will be further clarified by the following examples, which are intended to be purely exemplary of the invention.

[0081] The wax content of the oil set forth in the following Examples was determined as follows:

300 g of oil was diluted 50/50 with a 4:1 mixture of methyl ethyl ketone and toluene which was cooled to -20°C in a refrigerator. The mixture was filtered through a Coors funnel at -15°C using Whatman No. 3 filter paper. The wax was removed from the filter and placed in a tared 2 liter flask. The solvent was removed on a hot plate and the wax weighed.

#### Example 1

[0082] SAPO-11 was prepared as follows:

472.4 g of 85%  $\text{H}_3\text{PO}_4$ , were added to 1208 g of distilled  $\text{H}_2\text{O}$  in a Teflon beaker in an ice bath. 816.8 g of aluminum isopropoxide  $[\text{Al}(\text{OC}_3\text{H}_7)_3]$  were slowly added with mixing and then mixed until homogenous. Then 120 g of fumed silica (Cabosil M-5) were added with mixing. Next, 182.4 g of di-n-propylamine ( $\text{Pr}_2\text{NH}$ ) were added, followed by 9.0 g of 85%  $\text{H}_3\text{PO}_4$ . Final mixing was done using a Polytron. The mixture had a pH of 6.5 and the following composition, expressed in molar ratio of oxides:

The mixture was placed in a Teflon bottle in a stainless steel pressure vessel and heated for 5 days at 200°C with no stirring and autogenous pressure. The supernatant liquid was removed and the product was filtered, washed with water, dried overnight at 121°C, and calcined in air for 8 hours at 566°C. The average crystallite size was less than 0.5 micron. The product was identified as SAPO-11 by X-ray diffraction analysis. Elemental analysis of the calcined sieve showed it to have the following anhydrous molar composition:

[0083] The sieve was bound with 35% Catapal alumina and made into 1/10 inch extrudate. The extrudate was dried 3 hours at 121°C, calcined in air for 4 hours at 454°C, then impregnated with 0.5% Pt (as  $\text{Pt}(\text{NH}_3)_4\text{Cl}_2\cdot\text{H}_2\text{O}$ ) by the pore-fill method. It was then dried for 2 hours at 93°C, 2 hours at 149°C, and calcined in air for 8 hours at 454°C. For the following examples, the catalyst was crushed and screened to 24-42 mesh.

#### Example 2

[0084] The catalyst of Example 1 was used to isomerize a 800 °F+ hydrocracked waxy vacuum gas oil (Table IX) at 2200 psig, 1 LHSV, and 8 M SCF/bbl once-through  $\text{H}_2$ . The catalyst was also run at 400 psig. The results are set forth in Table X and demonstrate that high lube yield at very low pour point is achieved by the present process. The data also evidences the substantial yield benefit from operating at a lower reactor pressure. Lube yield is

where the product has the same 5 LV% boiling point as the feed.

### Example 3

[0085] The catalyst of Example 1 was used to isomerize a slack wax derived from a 900°F+ hydrocracked vacuum gas oil (Table XI).

[0086] Conditions were 160 psig reactor pressure, 0.3 LHSV, and 8 M SCF/bbl once-through H<sub>2</sub>. At a catalyst temperature of 680°F, a -27°C pour point oil of 7.1 cSt viscosity at 100°C and 149 viscosity index was produced. Pour point reduction could be increased by raising the catalyst temperature. Figure 3 shows a plot of 700°F+ lube yield versus pour point, where 700°F+ lube yield is defined as:

$$\left\{ 1 - \frac{g_{700^\circ\text{F}+}(\text{feed}) - g_{700^\circ\text{F}+}(\text{product})}{g_{700^\circ\text{F}+}(\text{feed})} \right\} \times 100\%$$

[0087] Figure 4 shows a plot of viscosity index versus pour point.

[0088] A -30°C pour point oil prepared in this example was subsequently hydrofinished over a 0.5% Pd on silica-alumina catalyst at 500°F, 2200 psig,

Example 6

[0091] ZSM-22 was prepared as follows:

[0092] The following reactants were combined to produce a gel: N,N'-dimethyl imidazolium hydroxide, Ludox AS-30 silica sol, aluminum sulfate, sodium hydroxide, and water in the ratios:

$$\text{SiO}_2/\text{Al}_2\text{O}_3 = 100$$

$$\text{H}_2\text{O}/\text{SiO}_2 = 30$$

$$\text{template}/\text{SiO}_2 = 0.15$$

$$\text{NaOH}/\text{SiO}_2 = 0.10$$

$$\text{OH}^-/\text{SiO}_2 = 0.25$$

The reaction was run at autogenous pressure in a stainless steel autoclave at 150°C for 6 days. The product was filtered, calcinated to 1000°F in air, ion-exchanged four times with excess  $\text{NH}_4\text{NO}_3$  and calcined again to 1000°F. The product was identified by X-ray diffraction analysis as ZSM-22. The  $\text{SiO}_2/\text{Al}_2\text{O}_3$  mole ratio was about 100. The sieve was bound with 35% Catapal and the extrudate impregnated

with 1% Pt and calcined in the same manner as the catalyst of Example 1.

### Example 7

- 5    **[0093]** The catalyst of Example 6 was used to isomerize the slack wax of Table XI at 500 psig, 0.3 LHSV, and 8M SCF/bbl once-through  $H_2$ . The results are set forth in Table XVII.

### Example 8

- 10    **[0094]** The catalyst of Example 6 was mixed with a 10-fold excess of 5 wt.%  $Mg CO_3$  in water, filtered, dried for 18 hours at 93°C, and calcined for 12 hours at 538°C. The Mg content was 22.7 wt.%. This catalyst was used to isomerize the slack wax of Table XI at 0.3 LHSV and 8 MSCF/bbl  $H_2$ , both at 500 psig and 160 psig. The results are set forth in Table XVIII, showing a higher yield for this catalyst than

that of Example 6 without Mg. The beneficial effect of low pressure on yield is also shown.

#### Example 9

- 5 **[0095]** The catalyst of Example 6 was used to isomerize a deoiled slack wax derived from a 900°F+ solvent refined vacuum gas oil (Table XIX). Conditions were the same as Example 7. The results are set forth in Table XX.

#### Example 10

- 10 **[0096]** The catalyst of Example 8 was used to isomerize a slack wax (not deoiled) derived from a 700-800°F solvent refined vacuum gas oil (the same used to prepare the feed of Table XII). Inspections of the feed are given in Table XXI. Isomerization conditions were the same as in Example 7. The results are set forth in Table XXII.

#### Example 11

- 15 **[0097]** ZSM-23 was prepared as in U.S. Patent No. 4,076,842, and identified as such by X-ray diffraction analysis after calcination at 1000°F in air. It was exchanged four times with excess  $\text{NH}_4\text{NO}_3$  and calcined again at 1000°F. The sieve was impregnated with 0.5% Pt and calcined in the same manner as the catalyst of Example 1.

[0100] While the invention has been described in connection with specific embodiments thereof, it will be understood that it is capable of further modification, and this application is intended to cover any variations, uses, or adaptations of the invention following, in general, the principles of the invention and including such departures from the present disclosure as come within known or customary practice in the art to which the invention pertains and as may be applied to the essential features hereinbefore set forth, and as fall within the scope of the invention and the limits of the appended claims.

# Claims

1. A process for producing lube oil comprising isomerizing a waxy feed 1) having greater than 50% wax and/or 2) exhibiting a high pour point above 0°C and having greater than 70% paraffinic carbon over a catalyst comprising a molecular sieve having generally oval 1-D pores having a minor axis between 4.2 Å and 4.8 Å and a major axis between 5.4 Å and 7.0 Å and at least one Group VIII metal at a pressure of from 205 kPa (15psig) to 13900 kPa (2000 psig).
2. The process of claim 1, wherein said waxy feed contains at least 80% wax.
3. The process of claim 1, wherein said waxy feed contains at least 90% wax.
4. The process of claim 1, wherein said waxy feed contains at least 80% paraffinic carbon.
5. The process of claim 1, wherein said waxy feed contains at least 90% paraffinic carbon.
6. The process of claim 1, wherein said waxy feed is selected from the group consisting of gas oil, lubricating oil stock, synthetic oil, foos oil, slack wax, deoiled wax, normal alphaolefin wax and microcrystalline wax.
7. The process of claim 1, wherein said molecular sieve is selected from the group consisting of SAPO-11, SAPO-31, SAPO-41, ZSM-22, ZSM-23, and ZSM-35 and said metal compound is selected from the group consisting of at least one of platinum and palladium.
8. The process of claim 7 wherein said molecular sieve further comprises a platinum hydrogenation component.
9. The process of claim 1, wherein said molecular sieve is a SAPO-11 crystalline silicoaluminophosphate.
10. The process of claim 9 wherein said molecular sieve further comprises a platinum hydrogenation component.
11. The process of claim 1, wherein isomerization is carried out at a temperature of from 200°C to 475°C and a pressure of from 205 kPa (15 psig) to 13900 kPa (2000 psig).
12. The process of claim 11, wherein said pressure is from 446 kPa 50 to 7000 kPa (1000 psig).
13. The process of claim 11, wherein the temperature is from 250°C to 450°C and the pressure is from 793 kPa (100 psig) to 4240 kPa (600 psig).
14. The process of claim 1, wherein the liquid hourly space velocity during isomerization is from 0.1 to 20.
15. The process of claim 14, wherein the liquid hourly space velocity is from 0.1 to 5.
16. The process of claim 1, wherein isomerization is carried out in the presence of hydrogen.
17. The process of claim 1, further comprising hydrofinishing the isomerized lube oil.
18. The process of claim 1, wherein hydrofinishing is carried out at a temperature of from 190°C to 340°C and a pressure of from 2860 kPa (400 Psig) to 20800 kPa (3000 psig).
19. The process of claim 18, wherein hydrofinishing is carried out in the presence of a metallic hydrogenation catalyst.

20. The process of claim 1, wherein said waxy feed has an organic nitrogen content of less than 50 ppmw.
21. The process of claim 20, wherein said organic nitrogen content is less than 10 ppmw.
- 5 22. The process of claim 1, wherein the waxy feed comprises C<sub>20</sub>+ paraffins and boils above 230°C.
23. The process of claim 22, wherein the waxy feed boils above 315°C.
24. The process of claim 1, wherein said molecular sieve is a ZSM-22.
- 10 25. The process of claim 24, wherein said molecular sieve further comprises a platinum hydrogenation component.
26. The process of claim 1, wherein said catalyst contains a Group IIA metal.
- 15 27. A process according to claim 1, wherein the molecular sieve is an intermediate pore size nonzeolitic molecular sieve containing AlO<sub>2</sub> and PO<sub>2</sub> tetrahedral oxide units.
28. The process of claim 27, wherein said waxy feed contains at least 80% wax.
- 20 29. The process of claim 27, wherein said waxy feed contains at least 80% paraffinic carbon.
30. The process of claim 27, wherein said waxy feed is selected from the group consisting of gas oil stock, lubricating oil stock, synthetic oil, foote oil, slack wax, deoiled wax, normal alphaolefin wax and microcrystalline wax.
- 25 31. The process of claims 27, wherein the liquid hourly space velocity during isomerization is from 0.1 to 20.
32. The process of claims 27, further comprising hydrofinishing the isomerized lube oil.
33. A lube oil obtainable by the process of claim 1 in which the waxy feed is a waxy petroleum hydrocarbon feed, having a pour point below -24°C and a viscosity index above 125.
- 30 34. A lube oil as set forth in claim 33 having a viscosity index of from 125 to 180 and a pour point of from -63°C to -24°C.
- 35 35. The lube oil of claim 34, wherein the viscosity index is at least 130.
36. The lube oil of claim 33 wherein the viscosity index is at least 140 and the pour point is no greater than -30°C.
37. The lube oil of claim 36, wherein the pour point is no greater than -40°C.

#### Patentansprüche

1. Verfahren zur Herstellung von Schmieröl, umfassend das Isomerisieren einer wachshaltigen Beschickung, die 1) mehr als 50% Wachs enthält und/oder 2) einen hohen Fließpunkt über 0°C aufweist und mehr als 70% Paraffin-  
45 kohlenstoff hat über einen Katalysator, enthaltend ein Molekularsieb mit im Wesentlichen ovalen 1-D-Poren, die eine Nebenachse zwischen 4,2 und 4,8 Å haben und eine Hauptachse zwischen 5,4 und 7,0 Å und mindestens ein Metall der Gruppe VIII bei einem Druck von 205 kPa (15 psig) bis 13900 kPa (2000 psig).
2. Verfahren nach Anspruch 1, wobei die wachshaltige Beschickung mindestens 80% Wachs enthält.
- 50 3. Verfahren nach Anspruch 1, wobei die wachshaltige Beschickung mindestens 90% Wachs enthält.
4. Verfahren nach Anspruch 1, wobei die wachshaltige Beschickung mindestens 80% Paraffin-Kohlenstoff enthält.
- 55 5. Verfahren nach Anspruch 1, wobei die wachshaltige Beschickung mindestens 90% Paraffin-Kohlenstoff enthält.
6. Verfahren nach Anspruch 1, wobei die wachshaltige Beschickung ausgewählt ist aus der Gruppe aus Gasöl, Schmierölausgangsmaterial, synthetischem Öl, Sedimentöl, Rohparaffin, entöltem Wachs, gewöhnlichem Alpha-

olefinwachs und mikrokristallinem Wachs.

7. Verfahren nach Anspruch 1, wobei das Molekularsieb ausgewählt ist aus der Gruppe aus SAPO-11, SAPO-31, SAPO-41, ZSM-22, ZSM-23 und ZSM-35 und die Metallverbindung ausgewählt ist aus der Gruppe aus mindestens einem aus Platin und Palladium.  
5
8. Verfahren nach Anspruch 7, wobei das Molekularsieb zudem einen Platin-Hydrierungs-Bestandteil enthält.
9. Verfahren nach Anspruch 1, wobei das Molekularsieb ein kristallines SAPO-11-Silikoaluminiumphosphat ist.  
10
10. Verfahren nach Anspruch 9, wobei das Molekularsieb zudem einen Platin-Hydrierungs-Bestandteil enthält.
11. Verfahren nach Anspruch 1, wobei die Isomerisierung bei einer Temperatur von 200 bis 475°C und einem Druck von 205 kPa (15 psig) bis 13900 kPa (2000 psig) erfolgt.  
15
12. Verfahren nach Anspruch 11, wobei der Druck von 446 kPa (50 psig) bis 7000 kPa (1000 psig) ist.
13. Verfahren nach Anspruch 11, wobei die Temperatur von 250°C bis 450°C ist und der Druck von 793 kPa (100 psig) bis 4240 kPa (600 psig).  
20
14. Verfahren nach Anspruch 1, wobei die Raumstundenge-schwindigkeit während der Isomerisierung von 0,1 bis 20 ist.
15. Verfahren nach Anspruch 14, wobei die Raumstundenge-schwindigkeit von 0,1 bis 5 ist.  
25
16. Verfahren nach Anspruch 1, wobei die Isomerisierung in Gegenwart von Wasserstoff erfolgt.
17. Verfahren nach Anspruch 1, ferner umfassend das Hydrofinishing des isomerisierten Schmieröls.
18. Verfahren nach Anspruch 1, wobei das Hydrofinishing bei einer Temperatur von 190°C bis 340°C und einem Druck von 2860 kPa (400 psig) bis 20800 kPa (3000 psig) durchgeführt wird.  
30
19. Verfahren nach Anspruch 18, wobei das Hydrofinishing in Gegenwart eines metallhaltigen Hydrierungskatalysators erfolgt.  
35
20. Verfahren nach Anspruch 1, wobei die wachshaltige Beschickung einen organischen Stickstoffgehalt von weniger als 50 ppm, bezogen auf das Gewicht, enthält.
21. Verfahren nach Anspruch 20, wobei der organische Stickstoffgehalt weniger als 10 ppm, bezogen auf das Gewicht, beträgt.  
40
22. Verfahren nach Anspruch 1, wobei die wachshaltige Beschickung C<sub>20+</sub>-Paraffine umfasst und über 230°C siedet.
23. Verfahren nach Anspruch 22, wobei die wachshaltige Beschickung über 315°C siedet.  
45
24. Verfahren nach Anspruch 1, wobei das Molekularsieb ein ZSM-22 ist.
25. Verfahren nach Anspruch 24, wobei das Molekularsieb zudem einen Platin-Hydrierungs-Bestandteil enthält.
26. Verfahren nach Anspruch 1, wobei der Katalysator ein Metall der Gruppe IIA enthält.  
50
27. Verfahren nach Anspruch 1, wobei das Molekularsieb ein nicht-zeolithisches Molekularsieb mit mittlerer Porengröße ist, das AlO<sub>2</sub><sup>-</sup> und PO<sub>2</sub>-Tetraederoxideinheiten enthält.
28. Verfahren nach Anspruch 27, wobei die wachshaltige Beschickung mindestens 80% Wachs enthält.  
55
29. Verfahren nach Anspruch 27, wobei die wachshaltige Beschickung mindestens 80% Paraffin-Kohlenstoff enthält.

## EP 0 536 325 B1

30. Verfahren nach Anspruch 27, wobei die wachshaltige Beschickung ausgewählt ist aus der Gruppe aus Gasölausgangsmaterial, Schmierölausgangsmaterial, synthetischem Öl, Sedimentöl, Rohparaffin, entöltem Wachs, gewöhnlichem Alphaolefinwachs und mikrokristallinem Wachs.
- 5 31. Verfahren nach Anspruch 27, wobei die Raumstundenge-schwindigkeit während der Isomerisierung von 0,1 bis 20 ist.
32. Verfahren nach Anspruch 27, weiter umfassend das Hydrofinishing des isomerisierten Schmieröls.
- 10 33. Schmieröl, herstellbar nach dem Verfahren aus Anspruch 1, wobei die wachshaltige Beschickung eine wachshaltige Erdölkohlenwasserstoff-Beschickung ist, mit einem Fließpunkt unter  $-24^{\circ}\text{C}$  und einer Viskositätszahl über 125.
34. Schmieröl nach Anspruch 33 mit einer Viskositätszahl von 125 bis 180 und einem Fließpunkt von  $-63^{\circ}\text{C}$  bis  $-24^{\circ}\text{C}$ .
- 15 35. Schmieröl nach Anspruch 34, wobei die Viskositätszahl mindestens 130 ist.
36. Schmieröl nach Anspruch 33, wobei die Viskositätszahl mindestens 140 beträgt und der Fließpunkt nicht größer als  $-30^{\circ}\text{C}$  ist.
- 20 37. Schmieröl nach Anspruch 36, wobei der Fließpunkt nicht größer ist als  $-40^{\circ}\text{C}$ .

### Revendications

- 25 1. Procédé pour la production d'une huile lubrifiante, comprenant l'isomérisation d'une charge cireuse 1) comprenant plus de 50 % de cire et/ou 2) présentant un point d'écoulement élevé supérieur  $0^{\circ}\text{C}$  et comprenant plus de 70 % de carbone paraffinique, sur un catalyseur comprenant un tamis moléculaire ayant de manière générale des pores ovales 1-D ayant un petit axe de 4,2 Å à 4,8 Å et un grand axe de 5,4 Å à 7,0 Å, et au moins un métal du Groupe VIII, à une pression comprise dans l'intervalle de 205 kPa (15 psig) à 13 900 kPa (2000 psig).
- 30 2. Procédé suivant la revendication 1, dans lequel la charge cireuse contient au moins 80 % de cire.
3. Procédé suivant la revendication 1, dans lequel la charge cireuse contient au moins 90 % de cire.
- 35 4. Procédé suivant la revendication 1, dans lequel la charge cireuse contient au moins 80 % de carbone paraffinique.
5. Procédé suivant la revendication 1, dans lequel la charge cireuse contient au moins 90 % de carbone paraffinique.
- 40 6. Procédé suivant la revendication 1, dans lequel la charge cireuse est choisie dans le groupe consistant en un gas oil, une huile lubrifiante et une huile synthétique, une huile de ressuage, une paraffine huileuse, une cire déshuilée, une cire alpha-oléfine normale et une cire microcristalline.
- 45 7. Procédé suivant la revendication 1, dans lequel le tamis moléculaire est choisi dans le groupe consistant en SAPO-11, SAPO-31, SAPO-41, ZSM-22, ZSM-23 et ZSM-35, et le métal est au moins un des éléments du groupe consistant en platine et palladium.
8. Procédé suivant la revendication 7, dans lequel le tamis moléculaire comprend en outre un constituant d'hydrogénation au platine.
- 50 9. Procédé suivant la revendication 1, dans lequel le tamis moléculaire est un silico-aluminophosphate cristallin SAPO-11.
10. Procédé suivant la revendication 9, dans lequel le tamis moléculaire comprend en outre un constituant d'hydrogénation au platine.
- 55 11. Procédé suivant la revendication 1, dans lequel l'isomérisation est effectuée à une température comprise dans l'intervalle de  $200^{\circ}\text{C}$  à  $475^{\circ}\text{C}$  et une pression comprise dans l'intervalle de 205 kPa (15 psig) à 13 900 kPa (2000 psig).

## EP 0 536 325 B1

12. Procédé suivant la revendication 11, dans lequel la pression est comprise dans l'intervalle de 446 kPa (50 psig) à 7000 kPa (1000 psig).
- 5 13. Procédé suivant la revendication 11, dans lequel la température est comprise dans l'intervalle de 250°C à 450°C et la pression est comprise dans l'intervalle de 793 kPa (100 psig) à 4240 kPa (600 psig).
14. Procédé suivant la revendication 1, dans lequel la vitesse spatiale horaire de liquide au cours de l'isomérisation est comprise dans l'intervalle de 0,1 à 20.
- 10 15. Procédé suivant la revendication 14, dans lequel la vitesse spatiale horaire de liquide est comprise dans l'intervalle de 0,1 à 5.
16. Procédé suivant la revendication 1, dans lequel l'isomérisation est effectuée en présence d'hydrogène.
- 15 17. Procédé suivant la revendication 1, comprenant en outre l'hydrofinissage de l'huile lubrifiante isomérisée.
18. Procédé suivant la revendication 1, dans lequel l'hydrofinissage est effectué à une température comprise dans l'intervalle de 190°C à 340°C et une pression comprise dans l'intervalle de 2860 kPa (400 psig) à 20 800 kPa (3000 psig).
- 20 19. Procédé suivant la revendication 18, dans lequel l'hydrofinissage est effectué en présence d'un catalyseur métallique d'hydrogénation.
20. Procédé suivant la revendication 1, dans lequel la charge cireuse a une teneur en azote organique inférieure à 50 ppm en poids.
- 25 21. Procédé suivant la revendication 20, dans lequel la teneur en azote organique est inférieure à 10 ppm en poids.
22. Procédé suivant la revendication 1, dans lequel la charge cireuse comprend des paraffines en C<sub>20</sub>+ et bout à une température supérieure à 230°C.
- 30 23. Procédé suivant la revendication 22, dans lequel la charge cireuse bout à une température supérieure à 315°C.
24. Procédé suivant la revendication 1, dans lequel le tamis moléculaire consiste en une ZSM-22.
- 35 25. Procédé suivant la revendication 24, dans lequel le tamis moléculaire comprend en outre un constituant d'hydrogénation au platine.
26. Procédé suivant la revendication 1, dans lequel le catalyseur comprend un métal du Groupe IIA.
- 40 27. Procédé suivant la revendication 1, dans lequel le tamis moléculaire est un tamis moléculaire non zéolitique à diamètre des pores intermédiaire contenant des motifs d'oxydes tétraédriques AlO<sub>2</sub> et PO<sub>2</sub>.
28. Procédé suivant la revendication 27, dans lequel la charge cireuse contient au moins 80% de cire.
- 45 29. Procédé suivant la revendication 27, dans lequel la charge cireuse contient au moins 80% de carbone paraffinique.
30. Procédé suivant la revendication 27, dans lequel la charge cireuse est choisie dans le groupe consistant en un gas oil, une huile lubrifiante, une huile synthétique, une huile de ressuage, une paraffine huileuse, une cire dés-huillée, une cire alpha-oléfinique normale et une cire microcristalline.
- 50 31. Procédé suivant la revendication 27, dans lequel la vitesse spatiale horaire de liquide au cours de l'isomérisation est comprise dans l'intervalle de 0,1 à 20.
- 55 32. Procédé suivant la revendication 27, comprenant en outre l'hydrofinissage de l'huile lubrifiante isomérisée.
33. Huile lubrifiante pouvant être obtenue par le procédé suivant la revendication 1, dans laquelle la charge cireuse est une charge d'hydrocarbures paraffiniques dérivée du pétrole, ayant point d'écoulement inférieur à -24°C et un

## EP 0 536 325 B1

indice de viscosité supérieur à 125.

34. Huile lubrifiante répondant à la définition suivant la revendication 33, ayant un indice de viscosité compris dans l'intervalle de 125 à 180 et un point d'écoulement compris dans l'intervalle de -63°C à -24°C.

5

35. Huile lubrifiante suivant la revendication 34, dans laquelle l'indice de viscosité est au moins égal à 130.

36. Huile lubrifiante suivant la revendication 33, dans laquelle l'indice de viscosité est au moins égal à 140 et le point d'écoulement est non supérieur à -30°C.

10

37. Huile lubrifiante suivant la revendication 36, dans laquelle le point d'écoulement est non supérieur à -40°C.
